Analysis Questions

1. How would you improve the robot's algorithm to become more efficient?

The algorithm could count the amount of errors in the initial user_input to check if the robot may be faulty even before it checks any of the items.

2. What might an Industrial Engineer change in a real robot system?

An industrial engineer would use actual inputs from real world situations instead of a user string input, checking weight or perhaps scanning for markers on the items to indicate the response. Additionally, the string outputs for each criteria would lead to actual functions rather than just printing out strings in an industrial environment.
